Updated: April 22, 2019

In a [study by Shannon and colleagues](#), 160 ticks and blood samples were collected from 70 healthy cats brought to the Mid Atlantic Cat Hospital in Queenstown, Maryland. [1]

The authors found that the cats were carrying 3 species of ticks including 83 Lone Star ticks (*Amblyomma americanum*), 7 American dog ticks (*Dermacentor variabilis*) and 70 black-legged ticks (*Ixodes scapularis*.)

Out of the 160 ticks, 22 (13.8%) tested positive by PCR for *Bartonella* spp., *Borrelia burgdorferi*, or *Borrelia miyamotoi*. However, only 25 of the 70 cats were able to be fully tested.

Nine of those cats (36%) were positive for exposure to at least one of the following tick-borne pathogens: *Borrelia burgdorferi*, *Ehrlichia ewingii*, *Anaplasma phagocytophilum*, *Borrelia miyamotoi*, *Bartonella clarridgeiae* and *Bartonella henselae*.

“We also found at least one cat blood sample to test positive for antibodies to each of the four tick-borne agents we screened for,” the authors state.

According to the authors' review of the literature, the risk to pet owners is unclear. “Pet ownership has been implicated in vector-borne pathogen transmission and has been identified as a potential risk factor for such diseases in some studies, but not others.”

Nevertheless, screening for ticks may prove helpful, providing advanced warning of disease risk to humans “upon recognition of an uncommon or unexpected pathogen in a pet or pet-derived parasite,” Shannon concludes.

*Author's note: Keeping your cat indoors can prevent it from picking up ticks that could be passed onto you or other family members.*
